Dear Jim,

Three years ago you discussed with me a radio telescope to operate at about 250 megacycles. An assortment of adjacent frequencies were to produce multiple beams. The details I have forgotten. What became of this? Have any papers been published describing its operation or displaying the results?

By rather different and circuitous reasoning I seem to have arrived at a vaguely similar scheme to give multiple beams on my instrument at Bothwell. Perhaps I can learn something useful from your experiences.

Best regards,

Grote Reber.
