Abstract—We present about the remote sensing thermometer working at cryogenic temperature for a polarization modulator used in cosmic microwave background (CMB) polarization experiment. The polarization modulator employs a superconducting magnetic bearing (SMB) in order to realize a continuous rotation at cryogenic temperature with minimal heat dissipation. Therefore, the polarization modulator is required to realize a continuous rotation at cryogenic temperature with minimal heat dissipation.

A general contact type bearing, e.g. a ball bearing, makes a large heat dissipation due to the physical friction. Thus, the polarization modulator often employs a superconducting magnetic bearing (SMB) [8-9] in order to satisfy this stringent requirement. The SMB is contact-less levitation type bearing, which consists of a permanent magnet as a rotor and a superconductor array as a stator. It is possible to realize a contact-less continuous rotation at cryogenic temperature by combining the SMB with a synchronous motor, consisting of rotor permanent magnets and stator coils. The fundamental problem of the SMB is that it is hard to measure the temperature of the levitating and spinning rotor at the cryogenic environment. The temperature is crucial information to estimate the thermal loading from the HWP.

In this paper, we discuss the measurement method of the SMB rotor temperature at cryogenic temperature. We propose a novel idea to take an advantage of a temperature dependent nature in NdFeB permanent magnet. First, we calibrated the SMB rotor temperature at cryogenic temperature. We propose a novel idea to take an advantage of a temperature dependent nature in NdFeB permanent magnet. Then, we evaluated the thermometer performance with a calibration setup with small magnets. Then, we calibrated the thermometer using a calibration setup with small magnets. Finally, we evaluated the thermometer performance with a calibration setup with small magnets.

I. INTRODUCTION

One of the most important research topics in current cosmology and high-energy physics is to study the cosmic inflation theory [1,2]. The theory predicts a rapid expansion of the universe after ∼10-38 seconds from the beginning of the universe. The inflation theory predicts that primordial gravitational waves from the cosmic inflation left the characteristic pattern, called B-mode, in a polarization component of a cosmic microwave background (CMB). We can still measure the CMB in microwave range as the oldest light from the big bang. Therefore, the experimental verification of the inflation theory is possible by the precise measurement of the CMB polarization signal. In order to verify the inflation theory, there are many CMB polarization experiments on the ground, balloon, and satellite. The development of related technologies is advancing innovatively.

Since the CMB polarization signal is very weak compared with the intensity signal, we need some dedicated devices or strategies for the precise measurement. A polarization modulator is one of the important instruments to realize the precise measurement [3-7]. It consists of an optical element, a half-wave plate (HWP), and a mechanism that rotates it continuously. The polarization modulator is installed at an aperture of a telescope, and it modulates an incident polarization signal. The modulation is able to reduce the impact of 1/f noise to the detectors and to mitigate the systematic uncertainties due to the detector differential characteristics. The HWP has to be maintained at the cryogenic temperature, e.g. below 10 K, in order to reduce noise due to its thermal emission.

Therefore, the polarization modulator is required to realize a continuous rotation at cryogenic temperature with minimal heat dissipation.

The infrared radiation thermometer is widely used in the various application as a remote sensing thermometer. It measures an intensity of an infrared radiation emitted from an object. The intensity is translated to the object temperature. The

II. CRYOGENIC REMOTE SENSING THERMOMETERS

The infrared radiation thermometer is widely used in the various application as a remote sensing thermometer. It measures an intensity of an infrared radiation emitted from an object. The intensity is translated to the object temperature. The
infrared radiation from the rotor below 10K is significantly weak compared with room temperature. Thus, the detector of the thermometer has to be maintained in sub-Kelvin temperature for this application in order to ensure the sufficient sensitivity. However, installing a dedicated sun-Kelvin cooler for only this thermometer is not realistic.

As another proposal for remote sensing thermometer, we can consider a method of converting a physical wire to inductive contact. In this case, we can use a usual resistive thermometer for the temperature detection. As the readout of the resistive thermometer, an inductor is mounted on the spinning rotor. Another inductor or a SQUID sensor with bias current is mounted on the stator side. We can measure the induced electromotive force by mutual induction of the two inductors. Then, the obtained resistance is translated to the rotor temperature. This method has an advantage that the existing resistive thermometer can be used. However, it is necessary to make the distance of the two inductors as an order of a few µm in order to ensure the sufficient sensitivity. Thus, this method has a significant risk of a physical collision between a rotor and a stator.

The third method is to use a property of a NdFeB permanent magnet. The magnetic field of the NdFeB magnet has strong temperature dependence, especially at cryogenic temperature. Thus, it can be used as cryogenic remote sensing thermometer by installing NdFeB magnet on the rotor and measuring its magnetic field with a Hall sensor. This thermometer is suitable for the polarization modulator because the permanent magnet is already used as a rotor in the SMB.

In this paper, we focus on the third method, i.e. the permanent magnet (PM) thermometer. We describe the calibration method and the verification of the thermometer accuracy.

III. EXPERIMENTAL SETUP

We constructed two type of experimental setup, i.e. a calibration setup and an application setup using a φ ~ 400 mm SMB. We install these setups to each dedicated 4 K cryostat with a Gifford-McMahon (GM) cooler in order to maintain an environment below 10 K. The purpose of the calibration setup is to measure the magnetic field of the permanent magnet in the temperature range from room temperature to around 4 K. We prepared two kinds of permanent magnets, NdFeB (N52) and SmCo (R33H), manufactured by Shinetsu Magnet Inc. [10]. They are small pieces of 15 mm × 15 mm × 5 mm without surface treatment. One of the magnets is mounted on an aluminum jig, as shown in Fig. 2. A cryogenic Hall sensor (HGT-3010, Lakeshore [11]) and a resistive thermometer (CX-1010, Lakeshore [12]) are installed near the magnet. The whole setup is installed in the 4 K cryostat with the most inner shell size of 350 mm × 350 mm × 130 mm. We monitored the magnetic field and the temperature of the permanent magnet with different distances of 1, 2, and 3 mm from the magnet surface.

We conducted the φ ~ 400 mm SMB prototype [13-15] in order to evaluate the developed PM thermometer, as shown in Fig. 3. The SMB consists of a NdFeB permanent magnet as a rotor and a YBCO superconductor array as a stator. The magnet is formed into a ring shape with 16 segmented NdFeB magnets, assembling by a coating glass epoxy. The superconductor array is also formed into a ring shape with 20 three-seeded YBCO tiles, which is covered by a glass epoxy holder. Both the magnet and the superconductor are fabricated and assembled by ATZ [16]. The SMB system is installed in φ ~ 1 m 4 K cryostat with the GM cooler. The most inner shell diameter is φ = 850 mm. The cryogenic Hall sensor is installed on top side of the rotor in order to measure the magnetic field of the rotor magnet. The resistive thermometer and heater are mounted on the surface of
the rotor magnet. The temperature of the levitating rotor is controlled by the resistive heater. It is monitored by the resistive thermometer. The resistive thermometer and heater are connected with readout wires. Therefore, the rotor is not able to be spinning with this setup. In this setup, the PM thermometer consists of the installed cryogenic Hall sensor and the SMB rotor magnet. It is evaluated by comparing with the resistive thermometer. The conceptual design of the experimental configuration is shown in Fig. 4.

### Fig. 4
The experimental configuration to evaluate the PM thermometer. The cryogenic Hall sensor is installed top side of the levitating rotor. The resistive thermometer and heater are mounted on the surface of the levitating rotor. The rotor temperature monitored by the resistive thermometer, and it is controlled by the resistive heater. The PM thermometer consisting of the rotor magnet and the Hall sensor is evaluated by comparing with the resistive thermometer. The conceptual design of the experimental configuration is shown in Fig. 4.

### IV. RESULTS AND THERMOMETER PERFORMANCE

#### A. Calibration

A magnetic field from a permanent magnet has a cryogenic temperature dependence, which differs according to kinds of permanent magnets. We measure the dependence using the calibration setup, as shown in Fig. 2. In the application of the SMB, a rare earth magnet, e.g. NdFeB or SmCo, is often used taking the advantage of their strength of the magnetic field. Other magnets have risks in the cryogenic environment due to their low-temperature demagnetization and brittleness. Thus, the temperature dependences of the NdFeB and the SmCo magnets are measured as the representative permanent magnets.

#### Fig. 5
The temperature dependence of the magnetic field of the permanent magnet. The blue and green lines show NdFeB and SmCo permanent magnet, respectively. The dot lines show the result of the 10th polynomial fit. The vertical axis is normalized to the absolute values of the magnetic field of room temperature (290 K).

Fig. 5 shows the measurement result of the magnetic field with...
respect to the rotor temperature for the NdFeB and the SmCo magnets. The gradient of the measured dependence is shown in Fig 6.

From the thermometer point of view, the accuracy depends on the gradient of the variation of the magnetic field. Thus, the NdFeB magnet is suitable to use as PM thermometer compared with the SmCo magnet, as shown in Fig. 6. We use the measured shape of the Fig. 5 as the calibration curve of the PM thermometer. Once we measure the magnetic field of the NdFeB magnet, we can translate it to the temperature of the magnet. However, the strength of the measured magnetic field follows the distance between the Hall sensor and the permanent magnet. Thus, we also measured the temperature dependence with different distances of 1, 2 and 3 mm, as shown in Fig. 7.

B. Spin reorientation transition of NdFeB

The characteristic shape of the NdFeB magnet in Fig. 5 is known as a spin reorientation transition (SRT) [17-20]. The SRT represents a change of the magnetization direction toward the energy stable state in a crystal. The conceptual diagram of the SRT is shown in Fig. 8. The transition temperature of the NdFeB magnet is known as around 135 K. From the room temperature to the transition temperature, the NdFeB magnetic spin prefers the direction along the c-axis of its tetragonal crystal, i.e. an easy-axis. Below the transition temperature, this spin direction is away from the easy-axis by the canting angle \( \theta \), which depends on the magnet temperature. The maximum deviation of the angle is 30 degrees at 4.2 K. The cone defined by \( \theta \) is referred as an easy-cone. The magnetization direction is tilted by the SRT, and the installed cryogenic Hall sensor is sensitive to the vertical magnetic field. Therefore, the magnetic field rapidly decreases below the transition temperature. The SRT is due to the complex tetragonal crystal structure and the unusual combination of the magnetic anisotropy.

C. Performance test using the SMB prototype

We apply the developed PM thermometer to the \( \Phi \sim 400 \) mm SMB prototype. The experimental configuration is shown in Fig. 4. The SMB system is cooled down to around 4 K. We prepare a space of 5 mm between the rotor magnet and the YBCO stator as a levitation height. After the cooling, the rotor is released by the cryogenic actuators. The rotor is levitated by a Meissner effect and the position is fixed by a pinning effect of the type II superconductor. The rotor is slightly dropped from the initial levitation height due to a gravity effect. The dropping distance is estimated by the reduction rate of the magnetic field with respect to the distance between the rotor magnet and the permanent magnet.
cryogenic Hall sensor. Fig. 9 shows the reduction rate obtained by a static electromagnetic simulation [21].

There is no thermal contact with the levitating rotor except for the wires of the resistive thermometer and heater. The rotor temperature is increased by the resistive heater by applying a certain voltage and inputting the Joule heat. In order to cool the rotor, the rotor is re-gripped by the cryogenic actuators. During this increasing and cooling cycle of the rotor temperature, we continue to monitor both output signals from the resistive thermometer and from the Hall sensor as the PM thermometer.

The measured magnetic field is translated to the temperature using the calibration curve considering the dropping distance. Then, we evaluate the PM thermometer by comparing with the resistive thermometer. Fig. 10 shows the obtained temperatures from the resistive thermometer and from the PM thermometer as a function of time. The levitating rotor is gradually heated by biasing the resistive heater with different input powers of 0.5, 1.0 and 1.5 mW. There is a good agreement between two thermometers. The spikes in the PM thermometer output are due to the electrical noise changing the bias voltage. The linearity between the resistive and the PM thermometer is shown in Fig. 11. The temperature accuracy of the PM thermometer in the range from 4 K to 20 K is ± 0.4 K, which is defined by the standard deviation of the temperature variation.

V. DISCUSSIONS

We demonstrated the performance of the PM thermometer using the SMB prototype. The temperatures from the resistive thermometer and from the PM thermometer were consistent. The accuracy of the PM thermometer was calculated from the result. In this setup, the wires are connected to the resistive thermometer on the rotor. Thus, it is not possible to measure the rotor temperature during rotation. In order to adapt to the actual modulator, it is necessary to consider the effect of the magnetic field variation during rotation. There is a specific pattern in the magnetic field variation due to the segmented ring magnet in one rotation [18]. Thus, the average value of the variation can be used as the argument of the calibration function.

In addition, the displacement of the rotor magnet in the vertical axis due to gravity effect has to be considered. Since the calibration curve can be normalized by the distance between the rotor magnet and the Hall sensor, the displacement can be treated as the vertical geometry factor in the calibration curve.

Therefore, the output of the PM thermometer, $T$, can be represented as

$$T = F \left( \frac{1}{n} \sum_{0 \leq \theta < 2\pi} B_\theta \cdot G_Z \right),$$

where $F$ is the calibration function as shown in Fig. 5. $B_\theta$ is the measured magnetic field at angle $\theta$, and $n$ is the number of measurement points. $\theta$ can be reconstructed by an optical encoder. $G_Z$ is the geometry factor in vertical direction?

From the SMB performance point of view, the SmCo has an advantage to use as the rotor magnet compared to the NdFeB. In case of the NdFeB, the magnetic field pinned to the YBCO at the transition temperature of 94 K and the magnetic field of the rotor magnet below 10 K are about 10 % different. Thus, the SmCo which has less temperature dependence is suitable for the SMB. In this case, the rotor magnet is not able to use as the PM thermometer. However, it is sufficient for the PM thermometer to mount the small piece of the NdFeB magnet on top of the rotor, with installing the Hall sensor close to it. Since the measured magnetic fields are averaged as equation (1), the effect of the rotation is able to be ignored. The demonstration of this method will be followed up by future papers.

CONCLUSIONS

We proposed and developed the PM thermometer as the cryogenic remote sensing thermometer for the polarization modulator used in CMB polarization experiments. We measured the calibration curve between the magnetic field and the temperature using the small piece of the NdFeB magnet and the cryogenic Hall sensor. We confirmed that the characteristic dependence due to the spin reorientation transition of the NdFeB magnet. The calibrated PM thermometer is evaluated using the $\phi \sim 400$ mm SMB prototype comparing with the temperature from the resistive thermometer. We obtained the consistent result between the PM thermometer and the resistive thermometer. The temperature accuracy of the PM thermometer is $\pm 0.4$ K, which is sufficient for the actual application. We discussed that how to actually adapt the PM thermometer to the SMB of the polarization modulator. The spinning effect and the distance relationship between the magnet and the Hall sensor can be treated by using the average and the geometry factors. Therefore, we successfully developed the cryogenic remote sensing thermometer which is applicable to the SMB of the polarization modulator.
